**Physiological Effects of Rebound Therapy**

1) **Cardio-respiratory:**
   - There is a high demand on muscles to deal with the increased gravity produced on deceleration and in the control of movement required when gravity is in effect reduced, as in acceleration, causing an increase in the respiratory rate and, subsequently, the heart rate. As a direct consequence there is an upturn in venous and lymphatic drainage. The constant muscle work required to maintain position and balance increases the demand for oxygen.

2) **Muscle tone:**
   - In simplistic terms, trampolining generally causes an increase in postural muscle tone, simply to prevent falling over. In Rebound Therapy, the effect on muscle tone hypertonia or hypotonia can be varied by the trainer. Low ampliative input (below the point of bouncing) can be effective in reducing muscle tone by bombarding the muscle spindle in much the same way as vibration can effect a decrease in muscle tone. High amplitude bouncing can cause an increase in tone by stimulating the stretch receptors. The two properties can be used therefore to increase or decrease tone where required. The effect of the rebound activity on muscle tone can easily be observed in people with spasticity, either hemiplegic or athetoid, or in those with ataxia where tone can be seen to undergo change.

3) **Postural mechanism:**
   - Stimulation by bombarding the sensory systems through joints, muscles and skin can energy of the bed by the springs orhypotonia can be varied by the trainer. Low ampliative input (below the point of bouncing) can be effective in reducing muscle tone by bombarding the muscle spindle in much the same way as vibration can effect a decrease in muscle tone. High amplitude bouncing can cause an increase in tone by stimulating the stretch receptors. The two properties can be used therefore to increase or decrease tone where required. The effect of the rebound activity on muscle tone can easily be observed in people with spasticity, either hemiplegic or athetoid, or in those with ataxia where tone can be seen to undergo change.

4) **Postural mechanism:**
   - Stimulation by bombarding the sensory systems through joints, muscles and skin can...
improve the output to the important postural muscles.

4) Balance mechanism:
In creating a dynamic movement situation, so challenging balance mechanisms, observable improvement can be achieved. This is particularly relevant when working with adults where a dynamic balance situation is difficult to create in lying, sitting or kneeling.

5) Kinaesthetic awareness:
By the multiple stimulation of joints, pressure stretch receptors, skin, muscles etc., kinaesthetic awareness is improved, leading to improved body image and spatial awareness.

THERAPEUTIC EFFECTS OF REBOUND THERAPY

1) Effects on movement:
Movement can be facilitated at different stages of the bounce. The most active movement takes place at the top of the bounce where acceleration of the body equals the downthrust of gravity to allow a momentary “gravity-free” zone. A tiny body movement can produce a large effect with correctly applied bounce. Momentum and rhythm can be added to movement to help teach new movement skills and energise movement. Balance and equilibrium reactions can be achieved through stimulation of postural mechanisms; by creating a dynamic movement situation, protective and saving reactions can be developed. The anticipation of movement occurs because of the effects of timing, rhythm and momentum. An inhibiting or stimulating effect on muscle tone enables active movement to take place. By using good positioning and support, and appropriate and minimal stimulation, relaxation can be obtained.

2) Effects on perception:
Body image, body part awareness and positional sense are enhanced through tactile and joint sensation. Increased perception of body image, spatial awareness combined with rhythm, and movement itself, greatly develop co-ordination. The experience of movement into space with the return to stability, while remaining in control, provides an enriched learning experience for the motor-impaired person.

3) Communication:
Due to cardio-respiratory effects, vocalisation is increased - with exclamations and gasps. Eye contact and concentration are enhanced by the “focus effect”.

In summary, Rebound Therapy:
• Is fun
• Gives confidence in movement
• Is usually achievable (with appropriate targets/goal setting)
• Develops fitness
• Gives general confidence and a feeling of well-being

REBOUND THERAPY SKILLS FOR THE OPERATOR

In order to achieve effective results, the operators must have a certain level of skill themselves, particularly in:
• Balance and co-ordination of their own body and movement on the trampoline
• Control of the trampoline
• Being able to control the trampoline for someone else
• Being able to carry this out safely for both the client and operator

In addition, they must make a full and accurate assessment, and, from that assessment, use Rebound Therapy to achieve stated goals, which, as in any other learning situation, should be in small, achievable steps.

‘ReboundTherapy.org’ is the official body and international consultancy for Rebound Therapy, responsible for the development and provision of certified staff training courses.

For further information on arranging a staff training course, visit www.ReboundTherapy.org or email info@reboundtherapy.org or telephone 00 44 1342 870543.
